 Object recognition
 Object recognition</t

- Object recognition: capability of naming discrete objects in the world
- Why is it hard? Many reasons, including:
 - Real world is made of a jumble of objects, which all occlude one another and appear in different poses
 - There is a lot of variability intrinsic within each class (e.g., dogs)
- We will look at three methods:
 - Template matching
 - Bag of visual words
 - Neural network methods

RANSAC

Hough Transform

bject recognition

References

Information extraction

- Next step is to extract information from images, such as
 - Geometric primitives (e.g., lines and circles): useful, for example, for robot localization and mapping
 - Object recognition and scene understanding: useful, for example, for localization within a topological map and for high-level reasoning

RANSAC

Hough Transform

Information extraction

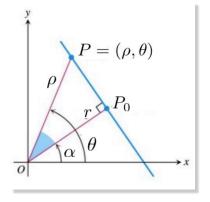

- Geometric feature extraction: extract geometric primitives from sensor data (e.g., range data)
- Examples: lines, circles, corners, planes, etc.
- We focus on line extraction from range data (a quite common task); other geometric feature extraction tasks are conceptually analogous
- The two main problems of line extraction from range data
 - Which points belong to which line? \rightarrow segmentation
 - Given an association of points to a line, how do we estimate line parameters? \rightarrow fitting

 Information extraction
 Split-and-merge
 RANSAC
 Hough Transform
 Object recognition

 0000000
 Step #2: line fitting

- Goal: fit a line to a set of sensor measurements
- It is useful to work in polar coordinates: $x = p \cos \theta$, $y = \sin \theta$
- Equation of a line in polar coordinates
 - Let $P = (p, \theta)$ be an arbitrary point on the line
 - Since P, P_0, O determine a right triangle

$$p\cos(\theta - \alpha) = r$$
 or $x\cos\alpha + y\sin\alpha = r$
(1)

• (r, α) are the parameters of the line

Split-and-merg

RANSAC

Hough Transform

Dbject recognition

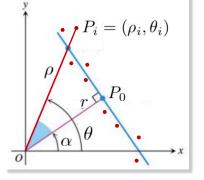

References

Step #2: Line Fitting

• Due to measurement errors, the equation of the line is only *approximately* satisfied:

$$p_i \cos(heta_i - lpha) = r + d_i \quad \longleftarrow _{\mathsf{Error}}$$

- Assume n measurement points represented in polar coordinates as (p_i, θ_i).
- Objective: Identify the line that best "fits" all the measurement points.

・ロト・西ト・山下・山下・山下・山下

 Information extraction
 Split-and-merge
 RANSAC
 Hough Transform
 Object recognition
 References

 Step #2: Line Fitting

- Assume that all measurements have equal uncertainty.
- Find line parameters r, α that minimize the squared error:

$$S(r,\alpha) := \sum_{i=1}^n d_i^2 = \sum_{i=1}^n (p_i \cos(\theta_i - \alpha) - r)^2$$

• Unweighted least squares

- Consider, now, the case where each measurement has its own, unique uncertainty
- For example, assume that the variance for each range measurement p_i is σ_i
- Associate with each measurement a weight, e.g., $w_i = 1/\sigma_i^2$
- Minimize

$$S(r,\alpha) := \sum_{i=1}^n w_i d_i^2 = \sum_{i=1}^n w_i (p_i \cos(\theta_i - \alpha) - r)^2$$

• Weighted least squares

 Information extraction
 Split-and-merge
 RANSAC
 Hough Transform
 Object recognition
 References

 Step #2: Line Fitting

- Assume that the *n* measurements are **independent**.
- Solution:

$$\alpha = \frac{1}{2} \operatorname{atan2} \left(\frac{\sum_{i} w_{i} p_{i}^{2} \sin 2\theta_{i} - \frac{2}{\sum_{i} w_{i}} \sum_{i} \sum_{j} w_{i} w_{j} p_{i} p_{j} \cos \theta_{i} \sin \theta_{j}}{\sum_{i} w_{i} p_{i}^{2} \cos 2\theta_{i} - \frac{1}{\sum_{i} w_{i}} \sum_{i} \sum_{j} w_{i} w_{j} p_{i} p_{j} \cos(\theta_{i} + \theta_{j})} \right) + \frac{\pi}{2}$$
$$r = \frac{\sum_{i} w_{i} p_{i} \cos(\theta - \alpha)}{\sum_{i} w_{i}}$$

• RANSAC: Random Sample Consensus

- General method to estimate parameters of a model from a set of observed data in the presence of outliers, where outliers should not influence the estimates of the values
- Typical applications in robotics: line extraction from 2D range data, plane extraction from 3D point clouds, feature matching for structure from motion, etc.
- RANSAC is **iterative** and **non-deterministic**: the probability of finding a set free of outliers increases as more iterations are used

RANSAC iterations

- In principle, one would need to check all possible combinations of 2 points in dataset
- If |S| = N, number of combinations is $\frac{N(N-1)}{2} \rightarrow$ too many
- However, if we have a rough estimate of the percentage of inliers, we do not need to check all combinations...

• Let w be the percentage of inliers in the dataset, i.e.,

$$w = \frac{\# \text{of inliers}}{N}$$

- Let p be the desired probability of finding a set of points free of outliers (typically, p = 0.99)
- Assumption: 2 points chosen for line estimation I selected independently
 - $P(\text{both points selected are inliers}) = w^2$
 - $P(\text{at least one of the selected points is an outlier}) = 1 w^2$
 - $P(\text{RANSAC never selects two points that are both inliers}) = (1 w^2)^k$

• Then, the minimum number of iterations \bar{k} to find an outlier-free set with probability, at least p is:

$$1-p=(1-w^2)^{ar k} \Rightarrow ar k=rac{\log(1-p)}{\log(1-w^2)}$$

- Thus if we know w (at least approximately), after \bar{k} iterations RANSAC will find a set free of outliers with probability p
- Note:
 - \bar{k} depends only on w, not on N!
 - More advanced versions of RANSAC estimate w adaptively

Hough Transform

- **Key idea:** Each point votes for a *set* of plausible line parameters.
- A line has two parameters: (m, b).
- Given a point (x_i, y_i) , the lines that could pass through this point are all (m, b) satisfying:

$$y_i = mx_i + b$$
, or $b = -mx_i + y_i$

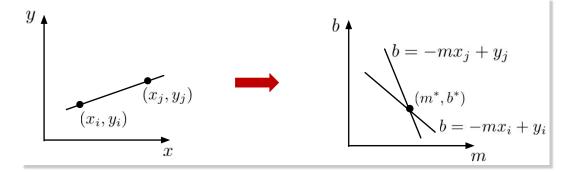

• A point in image space maps into a line in Hough space

• Key fact: all points on a line in image space yield lines in the parameter space which intersects at a *common point*, (*m**, *b**)
